DEKSIRIP: model and pilot proposal

Version 0.2 | 3 November 2026 | For academic criticism

DEKSIRIP in 5 minutes

The idea in one paragraph

DEKSIRIP is not a replacement for the whole economy. It is a testable model of local coordination. It tries to connect people with unmet basic needs to unused common resources through open information, predefined access rights, limited mandates and independent verification.

The problem

A resource can exist while a need remains unmet. Five links are often missing: information, an access rule, a priority decision, an executor and a check on the result. DEKSIRIP treats this as an organizational problem, not only a shortage of money or production.

How it works

need → verification of need and access rights → visible stocks, capacity, labour, costs and constraints → matching options against the physical balance → decision by residents and authorized operators → limited resources and staged execution → independent audit: promise → result → correction

Basic goods follow a predefined access rule. For projects beyond the basic level, goals, timelines, costs, risks and alternatives are published. Support can be released in stages and stopped when results deteriorate.

Example

Suppose a neighbourhood has spare kitchen capacity, food in storage and residents who lack prepared meals. The system does not begin by voting on every portion:

1. the need is recorded in aggregate form;
2. the store and kitchen publish actual stocks and constraints;
3. basic portions are provided under a pre-agreed rule;
4. spare capacity can be proposed for additional projects;
5. residents compare projects using published costs and expected results;
6. an audit compares promised volume, actual delivery and remaining stock.

If food is insufficient, the model does not promise the impossible. It shows the shortage, priority, alternatives and the basis for revising the decision.

What is common and what remains personal

- Common assets: selected public or collective resources whose returns are distributed under pre-agreed rules.

- Basic goods: a minimum set whose access does not depend only on ability to pay.

- Personal property: housing, belongings, income and assets outside the pilot mandate remain personal.

- Market and external economy: remain available for trade, comparison and exit from the pilot.

Who decides what

- residents state needs and participate in major changes;

- production teams manage daily operations;

- a coordination layer matches requests, resources and commitments;

- experts build scenarios and state uncertainty;

- auditors check data and outcomes;

- an AI assistant explains information and finds inconsistencies, but does not vote or control resources.

The more a decision affects other people and future resources, the stronger the requirements for publicity, justification and independent review.

What the model does not promise

It does not eliminate scarcity with one rule, replace professional management with universal voting or abolish all markets. Its narrower hypothesis is that a transparent link between need, resource, decision and outcome can improve local allocation and direct part of the surplus toward development.

What must be tested

The pilot must show whether access to basic goods improves, whether the gap between reported and actual resources narrows, whether participation paralyzes execution, and whether audit, appeal and the right to exit can stop a failing arrangement.

Concept Note: A Local Pilot for Transparent Common-Resource Allocation

Purpose: academic review and possible research collaboration Scope: voluntary local pilot; not a proposal for immediate national reform

To run something now: the pilot kit is executable by a cooperative, energy community, dormitory or small municipality without a host institution and without the author. This note describes the larger pilot that does need one.

1. Summary

This concept note proposes a small, voluntary and reversible pilot combining several mechanisms that have been tested separately in China and elsewhere: common or public ownership of selected productive assets, unconditional basic services, a resident social dividend, transparent cost information, voluntary project funding, strategic reserves and independent audit.

The proposal does not claim that these mechanisms are new individually. The research question is whether their combination can improve access to basic goods, productive investment and resilience while keeping decision-making visible and limiting rent extraction.

2. Research question

Can a bounded community coordinate production and allocation without either a central authority assigning every output target or private owners receiving a permanent claim on common productive assets?

3. Proposed institutional package

1. Basic provision. A defined basket of essential food, housing, healthcare and education is provided as a right of residence, subject to transparent capacity limits during the pilot.

2. Social dividend. Residents receive an equal periodic share of the pilot's distributable common product. The dividend does not confer ownership of land, factories or infrastructure.

3. Cost information. Published prices show physical cost, capacity, scarcity and relevant external damage rather than private profit.

4. Project funding. Residents may direct part of their discretionary share to proposals. Funding is released in stages and can be stopped when evidence changes.

5. Reserves. The community sets reserve targets for food, medicine, energy and other critical inputs before a crisis occurs.

6. Governance. Executives have limited mandates, are replaceable, and are subject to parallel audit and public reporting.

4. Pilot boundary

The pilot should begin with one locality, cooperative network or specially authorized development area. It should have:

- a defined resident population;

- a separable budget and asset register;

- legal authority for the selected services and assets;

- a conventional external economy for trade and comparison;

- an independent evaluation team;

- an accessible exit route for residents and participating organizations.

The pilot should not attempt to replace the national economy. Its purpose is to test a limited institutional interface and identify failure modes early.

5. Evaluation

The study should pre-register outcomes before implementation. Candidate measures include access to essential goods, household security, working time, productive output, project completion, reserve reliability, inequality, resident participation, trust, administrative cost and ecological impact.

Results should be compared with matched localities or with the locality's own pre-pilot baseline. A negative result is useful if it identifies which mechanism failed and under what conditions.

6. What this proposal is not

- not a request to adopt a complete ideology;

- not a claim that China has no relevant experience;

- not a plan to remove all markets or professional administration;

- not a promise that transparency eliminates political conflict;

- not a request for implementation before legal, ethical and economic review.

7. Requested collaboration

Researchers are invited to challenge the model, identify Chinese precedents, redesign the pilot boundary, specify legal constraints, propose control groups and estimate whether the package is testable at all.

The desired first outcome is a research critique, not an endorsement.

Questions, sources and contact

Questions for a researcher

1. Is the economic hypothesis clear and testable? Which assumptions are incompatible?

2. Which Chinese or international cases are closest to this combination of institutions?

3. Which work incentives, scarcity-allocation rules and boundaries of responsibility need clarification?

4. What minimal pilot, comparison and stopping criteria could produce credible evidence?

Official sources and limits of inference

[1] National Development and Reform Commission, 23 March 2023. Notice on the first set of typical practices from Zhejiang's common-prosperity demonstration zone (No. 252). Describes selected practices, including narrowing disparities and equalizing basic public services.

[2] Ministry of Finance of China, 25 January 2024. Report on common-prosperity village pilots in Pinghu. Describes joint financing, collective-asset use and income distribution, with reported project results and forecasts.

These documents establish individual practices. They do not prove the effectiveness or novelty of the full DEKSIRIP model, or the absence of a similar experiment. This is an initial reading list, not a systematic review; independent causal evaluation is still needed.
